Exo-Skeletal vs. Endo-Skeletal Explanations: Syntactic Projections and the Lexicon

HAGIT BORER
UNIVERSITY OF SOUTHERN CALIFORNIA

1 Introduction

Within generative traditions, the dominant approach to the projection of argument structure crucially links it to information in the lexical entry of argument selecting heads (verbs, adjectives, possibly nouns). Various executions of this leading idea may vary. Thus within many approaches, the argument structure associated with a particular lexical head is derived from the lexical semantics of that head (Jackendoff, 1990; Levin and Rappaport-Hovav, 1995; Carrier and Randall, 1992, among many others); within other approaches, the argument structure of a verb is a formal object, subject to formal manipulations, which do not represent direct mapping from lexical semantics (Williams, 1981; di Sciullo and Williams, 1987; Grimshaw, 1990; Reinhart, 1996, 2000). These approaches also differ on how argument-structure changing functions operate and where: in the lexicon, on lexical entries, as in Williams, (1981); di Sciullo and Williams (1987); Levin and Rappaport-Hovav (1995); Grimshaw (1990); Reinhart (2000) or alternatively, there are no argument structure changing functions as such, and what appears to be argument structure changing operations are the result of syntactic manipulations such as incorporation, as in the UTAH tradition, largely influential since Baker (1985, 1988). These approaches also differ on the nature of the relevant semantic roles (agent, theme, goal, etc., or alternatively, subject of change, subject of result, path, etc.). It is nevertheless fair
to say that they all do have in common the assumption that the original, crucial locus for argument structure specification is a lexical entry of an assignor, and that at least some level of structure, whether syntactic or lexical, projects directly from that entry.

In (1), I give a somewhat schematized representation of this class of approaches:

(1)  (Semantics of Lexical item $\rightarrow$) Predicate-Argument structure $\rightarrow$ structure (syntactic or lexical)

Consider, however, another approach, according to which much, if not the entire burden of argument structure is shouldered by the syntax. To consider a simple illustration, suppose it is not the case that agents project externally (universally), but rather, that nominal expressions which project externally must be interpreted as agents. Put differently, the syntactic structure gives rise to a template, or a series of templates, which, in turn, determine the interpretation of arguments. Within such approaches lexical items do not determine structure, but rather, function as its modifiers. Traditionally, this is a position that is associated with Construction Grammar (Fillmore and Kay, 1997; Goldberg 1995). More recently it has come to be associated with a number of models (often referred to as neo-constructionist models) which share to a varying degree a view of the grammar in which at least some argument structure interpretation is divorced from the lexical entry and rather, is determined by the structure. (see van Hout, 1992, 1996; Borer, 1994, 1998; Kratzer, 1994, 1996; Marantz, 1996, 1997; Harley, 1995; among others). Focusing here on the universal execution of this research agenda, the picture put forth within such models could be schematized as in (2):

(2)  Syntactic structure $\rightarrow$ event structure $\rightarrow$ interpretation of arguments

Reaching beyond the representation of argument structure, the lexicon-driven approach and the syntax-driven approach are but the tip of a much deeper theoretical iceberg. Assumptions concerning the division of labor between the lexicon and various computational systems have always played a crucial role within linguistic theories. At one extreme of the continuum from lexicon to computation, we find a view of the human linguistic capac-

---

1 Nor is this assumption unique to the Extended Standard Theory, or GB and its direct descendant. It also characterizes Lexical Functional Grammar (LFG) and Head-Driven Phrase Structure Grammar (HPSG).
ity fundamentally anchored in our demonstrable ability to acquire an intricate lexicon, based, at least in part, on a complex conceptual system. Within such a view, formal properties are deterministically projected from a listed item with fully articulated lexico-semantics, syntactic and morphological properties. Such properties include not just argument structure, but also syntactic category, syntactic projection environment, and morphological information. I will refer to such approaches as *endo-skeletal*, focusing, as they do, on the listed item as the skeleton around which the structure is built.

At the other extreme, we find a view anchored in our equally demonstrable rule-governed behavior. Such approaches assume a linguistic ability which is fundamentally computational, with as small as possible repository of idiosyncratic information appended to it, by means of a lexicon, beyond the clearly arbitrary pairing of sound and meaning. While most grammatical models occupy some intermediate place on this continuum, it is, I believe, fair to say that these two extreme positions characterize what counts as a linguistic explanation within most models. Here, I will take a strong computational position.

It is in the nature of things that an endo-skeletal approach, with its ability to associate idiosyncratic as well as unpredictable syntactic properties with atomic listed lexical items, is both less restricted and more redundant, but also, potentially, more capable, at least prima facie, of describing the wealth of phenomena attested in natural language. Nonetheless, even it turns out that some pairing of (some) listed items with syntactic properties is inevitable, the cause of explanatory adequacy could be greatly served by a systematic investigation of the extent to which the structure does determine the syntactic environment of inserted listed items, rather than the other way around. To this end, I will be pursuing here at least some of the consequences and the predictions of a strong computational position, illustrating specifically both modes of execution as well as a number of empirical advantages of such an approach.

More specifically, I will suggest that syntactic properties typically associated with listed items, notably argument structure and category type, are, in fact, properties of structures and not properties of the listed items themselves. While listed items may still convey an idea (e.g., *potato* is distinct from *pumpkin*), I will attempt to reduce as many as possible of the formal properties traditionally attributed to lexical listing to formal computational systems, be they syntax or morphology. I will call this view *exo-skeletal*, given its focus on the way in which the structure, rather than the listed item, determines not only grammatical properties, but also the ultimate fine-grained meaning of lexical items themselves (an effect at times called *coer-
If successful, then, an exo-skeletal research program is looking at a highly impoverished substantive lexicon which is a true interface with the conceptual system, and which contains little beyond the sound-meaning pair.

2 The Exo-Skeletal Approach

Consider the following execution of an exo-skeletal research program. Within such an approach there is a reservoir of sound-meaning pairs, where by meaning we refer to the appropriate notion of a concept, and where by sound we mean an appropriately abstract phonological representation. Following tradition, I will refer to that reservoir as the encyclopedia, and to items within it as encyclopedic items (EIs). Crucially, an EI is not associated with any formal grammatical information concerning category, argument structure, or word-formation. It is a category-less, argument-less concept, although its meaning might give rise to certain expectations for a felicitous context. It is EIs that are initially selected to form part of what I will call the conceptual array. In the absence of a category determination, however, they are inserted as an unordered set into an unmarked lexical phrasal domain (L-DOMAIN, L-D), as in (3):

\[
\text{\texttt{L-D}} \quad \text{sink, boat, dog}
\]

Alongside the encyclopedia and distinct from it the grammar does have a functional lexicon, including, in essence, grammatical formatives in the form of features (e.g., [+pl], [+pst]) as well as independent grammatical formatives (e.g., <the, [+def]>. Simplifying somewhat (but see Borer, 2001, 3 With special thanks to Henry Davis for having suggested the term exo-skeletal for this specific research agenda.

We are making no claims here on the organization of conceptual systems, assuming this important issue to be within the domain of psychological and/or philosophical studies, but clearly extra-linguistic. We only claim that the conceptual system, however internally organized and constrained, is the appropriate input to the sound-meaning pairing.

It is within the domain of ‘felicitous context’ that we locate the selectional restrictions of Chomsky’s (1965) Aspects model, assuming them to be fundamentally conceptual and not grammatical. We note that selectional restrictions can, and are regularly over-ridden by the grammatical environment (i.e., coerced), but that the opposite is never true. Thus a noun with a denotation of ‘stuff’ (e.g., sand) will receive a count interpretation in the context of a plural marking or plural agreement (e.g., many sands), but a plural-marked noun will never receive a mass interpretation, no matter how salient the context (compare too little carpet for the money with *too little carpets for the money).
for a fuller discussion), we may say that some grammatical formative α merges with L-D, in turn projecting some functional structure. Particular functional structures, in turn, will categorize whatever L-D they dominate. Consider, as an illustration, α to be equivalent of some value for Tense, e.g. <pst>, in a language in which the verb is inflected for tense. The merge of <pst>, and L-D would give rise to the structure in (4):

\[(4) \quad [\text{sink, boat, dog}]\]

Assuming free copy and merger (and abstracting away from the covert nature of verb movement in English), any of the items in L-D may now merge a copy in T, but under standard assumptions, only one may do so. Whichever element moves will become the head of L-D, as it must be a head, having merged a copy in a head position. In turn, L-D will become a VP in the context [\text{sink, boat, dog}], making its head in T, as well as its copy effectively, a V. There only remains to be hoped that some post-derivational phonological storage area will be capable of dispensing, for the resulting V+<pst> structure, a well-formed phonological representation, for if it does not, the derivation would not converge and ungrammaticality would result.

As it turns out, in English, there will be a phonologically felicitous representation for all the heads in (4), should they choose to merge a copy in T:

\[(5)\]

\(\begin{align*}
\text{a.} & \quad [\text{sink} - <\text{pst}>_r] [\text{sink, boat, dog}] & \text{(sank)} \\
\text{b.} & \quad [\text{dog} - <\text{pst}>_r] [\text{sink, boat, dog}] & \text{(dogged)} \\
\text{c.} & \quad [\text{boat} - <\text{pst}>_r] [\text{sink, boat, dog}] & \text{(boated)}
\end{align*}\)

However, consider <fut> in English. A derivation in which an array item from L-D merges a copy in T would not converge due to the absence of an appropriate phonological representation for V+<fut>. On the other hand a well-formed derivation with a future interpretation could still result just in case the correct phonological formative <will> merges with T. Here as well, L-D will become VP in the context of TP. As for its head, if no relevant categorizing morphology can distinguish the items in L-D, any of them could, in principle, be the head. The structure will not, however, remain hopelessly ambiguous, quite simply because the non-head constituents will be themselves embedded under functional structure, categorizing them, so to speak, presumably as DPs or PPs. Should that not turn out to be the case the structure would become uninterpretable. The two modes of projecting functional structure, the one associated with English past tense, the other with

---

\(^5\) The affinity with Anderson (1992) should be self evident here.
36 / HAGIT BORER

English future, are, I believe, the two major strategies universally available. As is obvious, they do not characterize an inter-grammatical situation, but rather, an intra-grammatical one.

Schematically, then, our grammar looks as in (6):

\[
\text{(6) ENCYCLOPEDIA} \rightarrow [\text{conceptual array}]
\]

\[
\text{functional merge} \quad \rightarrow \quad \text{move+merge}
\]

The Great Phonological Dispenser

Categorizing, then, can be achieved by the phrase structure of functional projections, with straightforward examples given in (7):⁶

\[
\begin{align*}
(7) & \quad [d < \ldots > d \ [\text{dog}, \text{form}]] \quad \text{L-D} \rightarrow \text{NP} \\
& \quad [v < \ldots > v \ [\text{dog}, \text{form}]] \quad \text{L-D} \rightarrow \text{VP} \\
& \quad [a < \ldots > a \ [\text{dog}, \text{form}]] \quad \text{L-D} \rightarrow \text{NP}
\end{align*}
\]

In turn, categorizing can also be accomplished by a morphological structure (distinguished here from inflectional/functional features). Thus category-labeled morphemes such as –ation, -ize, -al, -full, etc. are members of the functional lexicon associated with a syntactic lexical category, and therefore can interact with the conceptual array. In turn, they not only carry a category themselves, but also categorize their morphological complements, should they happen not to have a category already:

\[
\begin{align*}
(8) \quad \text{Categorizing by Morphological Structure:} \\
& \quad \text{a. -ation, N, [I_v \ [\_\_\_\_\_]_]} \\
& \quad \text{b. N, N}
\end{align*}
\]

⁶ In English, and perhaps universally, there are no productive conversions with adjectives, productive adjectivizing typically requiring overt morphology. It would appear that for reasons that may or may not be English-specific, adjectives never originate as “pure” category-less EIs.
The morphological structures in (8) may operate on items of the conceptual array, in L-D, giving rise to (9), or alternatively, categorizing morphemes such as –ation or –al may merge independently in the syntax as N or A respectively, in turn heading an Nmax and Amax. In this latter case, head movement would take place, and the structures in (8) would be applied to the output of head movement, as in (10):

\[
\text{(9) a. } \text{dog, boat, form} \\
\text{b. } \text{dog, boat, } \text{[v, } \text{form} \text{]} \\
\]  

\[
\text{[v, } \text{form} \text{]} \text{-ize, } \text{[v, al, ]} \\
\]

In, (10), note, [v, form] becomes a noun through its morphological environment, in turn making its copy a noun, and the L-D dominating it, an NP.
As E1 do not in and of themselves have arguments, by assumption, I will assume that argument structure, an event complex, emerges through functional syntactic structure, which has the effect of verbalizing an L-D, in the intended sense, in some event complexes, and possibly adjectivizing some other L-Ds, in other event complexes (e.g. stative ones, but see fn., 6). Specifically, and following a somewhat simplified version of Borer (1994, 1998, 2001), by virtue of being in the specifier of ASP, sink in the structure in (11) is assigned a DP structure, thus allowing the merger of functional DP internal material (in this case, three). In turn, three sinks in [Spec,ASP] is assigned a subject-of-quantity interpretation, in essence, equivalent to an interpretation associated with undergoing a structured change. Boat, in turn is assigned DP structure in [Spec,TP] thus licensing the merger of DP internal functional material (i.e. the). It then moves from [Spec,TP] to [Spec,EP], where it is assigned the role of an originator (of a non-stative event). Finally, and more crucially from the perspective of our focus here, all the functional nodes in (11) are verbalizers, turning L-D into a VP and categorizing dog as a verb (for concreteness, we assume overt short movement of the verb in English to a functional position above ASP). See Johnson, 1991, Runner 1995, for discussion):

7 The terminology used in Borer (1994, 1998) is ASP, rather than ASP, as responsible for the assignment of ‘objective’ roles in telic contexts, and ASP, as responsible for the assignment of the originator role. See Borer (2001) for some discussion on the rationale for the modifications. The notion ‘undergoing structured change’ is clearly reminiscent of notions such as ‘incremental’ or ‘gradual’ theme, proposed in Dowty (1991) and Krifka (1992). In Borer (2001), however, I argue that subject-of-quantity need not be a theme, and that the change under consideration need not be incremental, as such.
The output of (11) is in (12a). Likewise, the conceptual array in (5), together with the grammatical formatives will, the, three, could, in principle, give rise to all the sentences in (12) and more. Some are, of course, more compatible with world knowledge, or with selectional restrictions, than others. This we believe, however, to be outside the domain of the computational grammatical system, and strictly within the conceptual domain. Syntactically, note, they are all unambiguous, in assigning to the first DP the role of originator and to the second DP the role of subject of quantity entirely independently of plausibility:

(12) a. the boat will dog three sinks  
    b. The dog will sink three boats  
    c. The boat will sink three dogs  
    d. Three sinks will boat the dog  
    etc.

A striking illustration of the malleability of EI is available from the following paradigm, from Clark and Clark (1979). Note that siren, to begin with, is turned verbal by the syntactic contexts in (13), in which, in turn, it clearly functions as a modifier of an action, largely interpreted through the syntactic structure, rather than the determinant of the argument structure combinations available:

We note that the focus here is not on the actual interpretation of arguments or the relevant functional structure, but on the fact that some such structure must exist if argument interpretation is to be assigned to DPs away from lexical listing.
(13) a. The factory horns sirenèd throughout the raid
    b. The factory horns sirenèd midday and everyone broke for lunch
    c. The police car sirenèd the Porsche to a stop
    d. The police car sirenèd up to the accident site
    e. The police car sirenèd the daylight out of me

It is worthwhile noting that if argument structure is determined by the structure and not by the projection of information in lexical entries, it may be the case that relationship between structure and argumental interpretation are fixed, but nevertheless, different for the same stem in different contexts. Thus, for instance, if the subject in the context of destructible is interpreted as a subject-of-state, but an object in the context of destroy is interpreted as a subject-of-quantity, there is no particular reason to assume that they are projected in the same structural position. If, however, as endocentric, UTAH-driven approaches would have it, destroy assigns an internal (theme) argument in all its realizations, we would be committed to claiming that in both destroy and destructible (and, of course, destruction), a theme argument is projected in an identical position. For the paradigm in (13) this would mean that all occurrences of siren would have to be syntactically derived from a common source, a rather difficult fit. If, however, siren has no independent properties, and the argument structure in which it is embedded is syntactically, rather than lexically, driven, no such problems emerge. From this perspective, then, an exo-skeletal approach is more descriptively adequate here as well as theoretically simpler, without any need for compromising restrictiveness.

3 Some Questions and Some Goals

Any model which attempts to redefine the way in which category and argument structure come to exist must show not only that it is prima facie plausible and that it has some explanatory potential, but also that it makes at least some predictions which are fundamentally distinct (and, hopefully, correct) from those made by the model which it attempt to replace. In what follows I will attempt to show that some such predictions do exist, both within the syntactic and the morphological domain. I will further attempt to refine further the notion of listed item, as it is used in this work, elaborating, specifically, on the interaction between the morpho-phonological properties of words and structures. The specific subject matter on which I will focus concerns properties of nominals in general and derived nominals in particular.
Consider some of the obvious questions that do arise in the context of the treatment of categorizing and argument structure sketched above. First, note that the derivation of e.g., \([s, dog]\) and \([v, dog]\), as described in (7), gives rise immediately to the question in (14):

(14) Is it necessary, or desirable, to postulate, for English, a \(\emptyset\) affixation rule mapping \(N \rightarrow V\) or \(V \rightarrow N\) (or alternatively, a rule of conversion mapping one to the other)? Alternatively, all such \(\emptyset\)-alternations are syntactically, rather than morphologically, determined, by inserting a category-neutral EI into a syntactically or morphologically deterministic structure. Even more importantly, does the assumption that \(dog\) is a category-neutral EI inserted into distinct syntactic environments have empirical consequences which are distinguishable from those which emerge if some categorical instance of \(dog\) (say the verb) is derived from the other?

Second, consider the issue of argument structure within derived nominals, and more specifically, the pair in (15):

(15) a. The enemy destroyed the city
    b. The enemy’s destruction of the city

As of Chomsky (1970), it is standardly assumed that the relations which holds between the noun \(destruction\) and \(the city\) in (15b) parallel, and indeed have the same lexical source, as those which hold between \(destroy\) and \(the city\) in (15a). The fact that in the case of (15a) it is a verb which is thus related to the object, but in (15b) it is a noun is theoretically insignificant in this context. Consider, however, the pair in (15) from the perspective of an account which attributes the interpretation of arguments to functional structure, which has, in turn, verbalizing (or adjectivizing) properties. If such an approach is on the right track, it means not only that the role of \(the city\) cannot be assigned by either \(destroy\) or \(destruction\), but also, that if, indeed, \(the city\) is assigned a role in (15b) on a par with the role assigned to \(the city\) in (15a) (e.g., in \([\text{Spec,ASP}], as \text{subject-of-quantity}\)), there must be a verbal constituent within (15b). Even more strongly, a strong semantic claim emerges from the specific syntactic execution here, according to which nouns, as such, may never have (event) argument structure, and every instantiation of (event) argument structure, by virtue of its categorizing properties, must include either a VP or an AP projection. Our next task, then, is to answer the question in (16):
(16) Can it be shown that there is, indeed, a verbal constituent in (15b), together with the relevant functional structure (as in e.g. (11)) responsible for the assignment of argument structure? Can it be shown that nouns, as such, never have (event) argument structure, and that (event) argument structure always require the projection of either a verbal or an adjectival constituent, in the relevant functional configuration?

In the following sections, I will address these issues. In sections 4-5 I review Grimshaw’s (1990) analysis of derived nominals, assuming her descriptive conclusions to serve as the starting point for any adequate future research on derived nominals. Nevertheless, her specific analysis, crucially embedded within a lexical approach to role assignment, is reviewed and rejected. The conclusions I reach are summarized in (17):

(17) a. So-called complex event nominals (in the sense of Grimshaw, 1990), are derived from the presence of a nominal structure above an argument structure event complex, including either a VP or an AP alongside functional structure, e.g. as in (i):

<i>\[
\text{[ N \text{-ation/-ing} \ [EP_APQ \ [L \_D \ldots L \_]]]}
\]</i>

In (i), ASP_Q as well as EP are verbalizers, and hence L-D is a VP. In turn, L(= V for (i)) merges with -ation/-ing and is (or is not) assigned morpho-phonological structure. More specifically, the event interpretation of complex event nominals cannot be a property of nouns or of nominalizing affixes as such, contra Grimshaw (1990).

b. So-called result nominals are derived from the presence of a nominal structure directly above the EI, projected within the conceptual array.

Having elaborated on the properties of nouns which are derived from verbs with overt affixation, I turn to the status of so-called Ø-affixation or conversion, and to the question posed in (14). I address this question specifically in the context of so-called Ø-derived nominals such as a walk, a talk, a drive, a break, etc. An examination of their properties, undertaken in section 6, leads to the conclusions in (18):

(18) a. Ø-marked N V alternations are not derivational, but represent category neutral EIs inserted in different syntactic environ-
ments. There is Ø categorically-marked affix in English (universally?)

b. The absence of ‘Ø-derived’ complex event nominals follows directly from the exo-skeletal model, combined with the absence of Ø-categorial affixation in English, and in fact, provides strong evidence for the particular exo-skeletal model proposed here.

Within a neo-constructionist or exo-skeletal approach, with its impoverished listed representations that are devoid of category and argument structure information, yet another important question arises, concerning the degree to which encyclopedic entries are phonologically abstract. To consider a concrete example, suppose we look at the pair eat-feed in English, semantically displaying a rather similar relation to that associated with sink.TRANSITIVE-sink.INTRANSITIVE. Could we assume that there is one EI, say EAT with appropriate semantic value but no phonological (or syntactic) properties, and which, depending upon the existence or lack thereof of a causative syntactic structure, would result in the picture in (19a-b):

\[
\begin{align*}
(19) \text{a.} & \quad [v, \text{EAT}] \rightarrow /\text{eat}/ \\
\text{b.} & \quad [v, \text{CAUSE}] [v, \text{EAT}] \rightarrow /\text{feed}/
\end{align*}
\]

The conclusion to be reached here, as based on the discussion of derived nominals, will be that the representation in (19) must be rejected. Rather, we will conclude that EIs must be associated with (at least some abstract) phonological matrix. While some phonological manipulation is possible, some degree of phonological faithfulness must be preserved. What is possible, I will argue, are stem allomorphs conditioned by different syntactic or morpho-phonological contexts, hence [\textit{destroy},] \Leftrightarrow [\textit{distruct}_{\text{d}}]; [\textit{pr\text{ö}gress},] \Leftrightarrow [\textit{pr\text{ö}gress}_{\text{d}}], and also [\textit{grow},] \Leftrightarrow [\textit{growth}_{\text{d}}],[\textit{high},] \Leftrightarrow \textit{height}_{\text{d}}) (but more on that below). Concretely, this means that /\textit{feed}/ and /\textit{eat}/ cannot be derived from the same EI. In turn, the existence of phonological repre-

---

1 The scope of the possible universal here should be made clear. I am not suggesting that grammatical distinctions are never available without overt phonological marking. The claimed potential universal here, if indeed, shown to exist, would involve exclusively the absence of overt marking in the presence of categorial change.

2 In turn, to the extent that pairs such as feed-eat may be morphologically related, and hence derived from the same EI in some languages, this means that the encyclopedia cannot be considered the conceptual system proper, but rather, a true interface in which the presence of entry is determined by the conceptual system together with arbitrary, language specific vocabulary choices.
sentation for EI will turn out to place well-defined morpho-phonological restrictions on what are and what are not syntactically possible derivations.

This paper concludes with a brief comparison between the specific neo-constructionist execution proposed in this paper and other neo-constructionist executions, arguing, specifically, that a verbalizing (or adjectivizing) function is associated with all (event) argument structure, contra Marantz (1997) and Alexiadou (1999), and that the functional structure responsible for interpreting ‘external’ arguments may occur inside derived nominals.

4 Referential Nominals vs. Argument-Structure Nominals

4.1 Grimshaw’s Diagnostics

Grimshaw (1990) diagnoses two types of nominals which I will refer to as AS-nominals (Grimshaw’s complex event nominals) and R-nominals (Grimshaw’s result nominals) respectively, and which are illustrated in (20)-(21). They have the properties in (22)-(23) respectively:

(20) AS-Nominals
    a. The instructor’s (intentional) examination of the student
    b. The frequent collection of mushrooms (by students)
    c. The monitoring of wild flowers to document their disappearance
    d. The destruction of Rome in a day

(21) R-Nominals
    a. The instructor’s examination/exam
    b. John’s collections
    c. These frequent destructions took their toll

\[\textit{\textsuperscript{10}}\text{The issue of the level of phonological abstractness of lexical items does not arise for strict lexicalist approaches, in which \textit{feed} and \textit{eat} are distinct lexical entries, but it does arise for approaches such as UTAH, in which }\textit{sink.\textsc{trans}}\text{ is derived from }\textit{sink.\textsc{intrans}}. \text{As such, the conclusion that we will reach here is not just applicable to neo-constructionist models, but to any model which denies the independent listing of, e.g., }\textit{sink.\textsc{trans}}\text{ and }\textit{sink.\textsc{intrans}}.\]
EXO-SKELETAL VS. ENDO-SKELETAL EXPLANATIONS / 45

(22)  **AS-Nominals (Argument Structure Nominals)**
   a.  θ-assignors, Obligatory arguments
   b.  Event reading
   c.  Agent-oriented modifiers
   d.  Subjects are arguments
   e.  By phrases are arguments; in Hebrew, selects *al-yedey*
   f.  Implicit argument control
   g.  Aspectual modifiers.
   h.  *frequent, constant* etc. possible without plural
   i.  Mass nouns

(23)  **R-Nominals (Referential Nominals)**
   a.  Non-θ-assignors, No obligatory arguments
   b.  No event reading
   c.  No agent-oriented modifiers
   d.  Subjects are possessives
   e.  By phrases are non-arguments; in Hebrew selects *šel (of) me’et*
   f.  No implicit argument control
   g.  No aspectual modifiers
   h.  *frequent, constant* etc. possible only with plural nouns
   i.  Count nouns

The most powerful support for the classification in (22)-(23) comes from the impossibility of mixing and matching properties. Thus in the presence of an argumental by-phrase, a modifier such as *constant* cannot take a plural noun, nor is the omission of an object possible in (24a). Likewise, without arguments for *destruction*, the modification in a day gives rise to ungrammaticality.

(24)  a.  *The constant examination(s) by the students*
   b.  *Mary’s frequent collection*
   c.  *The collection to document the disappearance of mushrooms*
   d.  *The destruction in a day*

To account for the differences between these two types of nominals, Grimshaw (1990) proposes that AS-nominals, her complex event nominals, have an event argument (*Ev*), and that the argument taking properties associated with the resulting nominal derive from the presence of such an event argument. On the other hand, R-nominals have a referential (*R*) external argu-
ment, responsible for the result interpretation associated with them. Fully endorsing the existence of two types of derived nominals, as argued by Grimshaw, there are, nevertheless, some problems with the idea that a noun may directly assign an event argument, or be associated with event structure, some pointed out in Grimshaw’s own work. First, as Grimshaw notes (op. cit.), many nominals which denote an event behave like R-Nominals, and not like AS-Nominals. Among these are nouns such as *event, metamorphosis, journey, trip, etc., as illustrated by (25):

(25) a. *The constant race to the mountains  
   b. *The event in three hours  
   c. *John’s deliberate trip to the mountains  
   d. *A race from the station by Mary  
   e. *The metamorphosis of the town in order to win a medal

That nouns such as *event, metamorphosis, journey, trip are, indeed, event denoting, and that this event denotation appears to have at least some linguistic consequences is indicated by the grammaticality of (26), vs. the impossibility of (27) under a similar event interpretation (coercion notwithstanding):

(26) a. The three different races from the stadium lasted a long time.  
   b. The metamorphosis of Paris will last into the next century

(27) *The table lasted a long time (under an event reading, coercion notwithstanding)

Similarly, the contrasts in (28a,b), assuming, following Reichenbach (1948), that happen, take place and occur can only be predicates of events:

(28) a. The trip/metamorphosis/event/journey occurred last night  
   b. *The table occurred last night (coercion notwithstanding)

Thus it is clear that an event denotation, to the extent that it plays a role, cannot in and of itself induce the diagnostics in (22), and some means are necessary to distinguish between the event nominals in (20) and the event nominals in (25). To this end, Grimshaw introduces a distinction between Complex Event Nominals (=AS-Nominals) and Simple Event Nominals, as in (25). The distinction, primarily, is based on argument structure. While Complex Event Nominals, Grimshaw suggests, assign a role to an event
argument \((Ev)\), Simple Event Nominals pattern with \(R\)-Nominals, in not assigning such a role, and instead, in assigning a role to a referential index, \(R\). Because in Grimshaw’s model derived nominals have a lexical entry which is independent of their derivational history, and because an entry for, e.g., \textit{transformation}, is in essence ambiguous between an \(AS\)-Nominal and an \(R\)-Nominal, the fact that some nouns denoting events (e.g., \textit{metamorphosis}) do not take arguments and do not assign an \(Ev\) role, while others (e.g., \textit{transformation}) do, becomes a matter of arbitrary lexical listing.

And yet the classification is anything but arbitrary. Only nouns which are derived from verbs (or as we shall see, from adjectives) by means of overt affixation can be \(AS\)-Nominals, while nouns which do not have a verbal or an adjectival source never are.\(^{11}\) Viewed from that perspective, one is certainly tempted to view argument structure as well as event interpretation as deriving from the source verb or adjective, rather than the noun itself. But if this is indeed the case, then it would follow that nouns, as such, are never the source of event interpretation or argument structure. At the very best, they could be viewed as vehicles for passing on the roles and properties of stems embedded within them.

The problems for identifying what, exactly, is the relevant notion of event so as to apply it successfully to the diagnostic in (22)-(23) are further compounded by the fact that many \(R\)-Nominals derived from verbs denote an event and behave just like Simple Event Nominals, as (29)-(30) illustrate (see Zucchi, 1989):

\begin{enumerate}
  \item The destruction lasted for hours
  \item The examination lasted for hours
\end{enumerate}

\begin{enumerate}
  \item The destruction occurred at dawn
  \item The exam(ination) took place at 5pm
\end{enumerate}

What, then, is the lexical entry of \textit{destruction}, such that it has two entries, both denoting event, but one which assigns an \(Ev\) role and the other an \(R\) role? We seem to be faced now with a difficulty which emerges directly from the assumption that an event interpretation is the basic property of the derived nouns themselves, from which the presence of argument structure derives.

And finally, we note that while \(AS\)-Nominals do need to have an event interpretation in the episodic sense, they need not be eventive and may be stative. Such is the case for nominals derived from adjectives, clearly in

\footnote{Attributing it to A. Zucchi (p.c.), Grimshaw notes this fact, but does not pursue its consequences.}
evidence whenever the adjective in question can occur with complements, directly carried over to the nominal derived from it, as (31)-(32) illustrate:

(31) a. The court’s awareness of the problem
    b. Pat’s consciousness of my presence
    c. Jill’s fondness of classical music
    d. Robin’s readiness to leave
    e. Marcia’s closeness to her parents
    f. The party’s satisfaction with the counting results

(32) a. The court is aware of the problem
    b. Pat is conscious of my presence
    c. Jill is fond of classical music
    d. Robin is ready to leave
    e. Marcia is close to her parents
    f. The party is satisfied with the counting results

The existence of de-adjectival AS-nominals poses some difficulties for the Grimshaw model. First, we note that of the diagnostics in (22) only those in (33) are clearly applicable to de-adjectival nominals:

(33) a. θ-assignors, Obligatory arguments
    d. subjects are arguments
    h. constant etc. possible without plural
       (No agent-oriented modifiers; no implicit argument control, no aspectual modifiers)

In turn, the derived nominals in (31) do not behave like R-nominals either. Their subject is an argument, rather than a possessor, constant need not occur with a plural, etc. This state of affairs raises an important issue concerning the generality of Grimshaw’s account. If Ev is assigned by the derived nominals in (31), the absence of event modification, event control, etc. becomes mysterious. If, on the other hand, Ev is not assigned by the derived nominals in (31), the presence of an argument structure identical to that of the source adjectives alongside the non-R-nominal properties of (31) must be argued to have a source distinct from the assignment of Ev. But if argument structure and non-R-properties can be assigned in (31) without an Ev argument, then the putative link between Ev and argument structure can no longer be generally maintained, and whatever mechanism is developed to account for the properties of (31) would need to be explicitly excluded in the domain of nominals derived from verbs.
One could suggest that some derived nominals assign \( Ev\)-\textit{stative} while others are assigned \( Ev\)-\textit{eventive}. In Grimshaw’s system, however, such assignment would have to be stated entirely independently of the derivational history of the relevant nouns, making the fact that stative interpretation is associated with nouns derived from adjectives, but not with nouns derived from verbs (and vice verse) a pure coincidence. In turn, of course, it could be suggested that the derived nominal inherits the nature of the \( Ev\) argument from the source verb or adjective, making a noun derived from an (eventive) verb \textit{eventive}, and a noun derived from an adjective \textit{stative}. That, of course, would be a fully workable solution, but here, again the conclusion must be that the source of any event interpretation as well as argument structure cannot be the derived nominal itself, but must be related in some fashion to the verb/adjetive from which it is derived.

Suppose, then, that we assume that the arguments as well as the type of event involved are related in some crucial sense to the event complex dominated by the \( AS\)-nominal, an event complex which is headed by the very \( L\)-stem which incorporates into the nominalizer. What would be the ramifications of such an approach? Note that it has immediate ramifications for the level of phonological abstractness of EIs, or, for that matter, lexical items. To the extent that \( AS\)-nominals are precisely those which are morphologically derived from phonologically attested verbs or adjectives, and reflect directly a morpho-phonological relationship with them, we must assume that at least in this case, we are dealing with phonologically concrete objects, and not just with an abstract set of semantic or conceptual features. To see that this is so, consider the following hypothetical derivation:

\[
\begin{align*}
(34) \text{a. } & \text{EI: } [\text{TRANSFORM}] \rightarrow [\text{TRANSFORM}] \rightarrow /\text{transform/} \\
& b. [\_\text{TRANSFORM}] + \text{NOM} \rightarrow [\text{TRANSFORMATION}] \rightarrow /\text{transformation/} \\
& c. [\_\text{TRANSFORMATION}] \rightarrow /\text{metamorphosis/; /shift/; /turn/ (etc.)} \\
\end{align*}
\]

Suppose, specifically, that an EI with the semantic and conceptual properties of [\text{TRANSFORM}] is inserted into an appropriate verbalizing structure, giving rise to [\text{TRANSFORM}]. Still maintaining its conceptual and semantic nature, now also associated with the syntactic category V, but still devoid of any phonological specification, [\text{TRANSFORM}] may now give rise to [\text{TRANSFORMATION}], associated with conceptual and semantic structure, as well as a category, but no phonological, or morpho-phonological information. However, whatever semantic and conceptual properties are associated with the noun [\text{TRANSFORMATION}] are also associated with [\_\text{SHIFT}], [\_\text{METAMORPHOSIS}] or [\_\text{TURN}], making the phonology of any of these nouns a proper phonological form for [\text{TRANSFORMATION}], in some post-derivational component. In turn, however, the derivation in (34c) must be
blocked. If it is allowed, we would predict, contrary to fact, that metamorphosis/shift/turn may have argument structure associated with the event complex headed by [\(-TRANSFORM\)]. While any ad hoc blocking of (34c) is, of course, possible, the near total absence of any such correlations, that is, the absence of phonological realizations for AS-nominals which do not record an actual morpho-phonological history of having been derived from a verb or an adjective, cannot be explained unless we assume that representations such as (34) must be rejected and replaced, at the very minimum, with the representations in (35), where \(\pi\) is a reference to an indexed phonological representation of some abstraction, and where EIs are sets referring both to some semantic/conceptual features and to some such phonological index.\(^{12}\)

(35) a. EI: (transform, \(\pi\) \(\rightarrow\) ([\(-TRANSFORM\)], \(\pi\) \(\rightarrow\) /transform/)
   b. ([\(-TRANSFORM\)], \(\pi\)+nom \(\rightarrow\) ([\(-TRANSFORMATION\)], \(\pi\) \(\rightarrow\) /transformation/)
   c. ([\(-TRANSFORMATION\)], \(\pi\) \(\rightarrow\) */metamorphosis/, /shift/, /turn/)

The contrasts in (36)-(37) illustrate a similar effect in Hebrew. Transformacia is a borrowed word, meaning ‘transformation’. Šinui is a (native Hebrew) nominal, derived from the verb šina, ‘change, transform’. While the latter can occur both as an AS-nominal and as an R-nominal, the former, without any morpho-phonological derivational history in the language, can occur only as an R-nominal:

(36) a. ha-šinui šel merkaz ha-’ir
   the-transformation/change of center the-city
   ‘al yedey ha-’iriya
   by city hall
b. ha-šinuy haya madhim
   the-change/transformation was amazing

(37) a. *ha-transformacia šel merkaz ha-’ir ‘al yedey ha-’iriya
   the-transformation of center the-city by city hall
b. ha-transformacia haya madhima

\(^{12}\) A reviewer objects that metamorphosis, shift, turn and transformation might, in actuality, be sufficiently semantically distinct so as to make their interchanging in (35) impossible. We note that while one may subscribe to the view that true synonyms do not exist, and every encyclopedic entry, or lexical entry is maximally unique, at least the Hebrew example below shows that what is at stake here is very clearly the derivational history, and not the cluster of relevant meanings.
The transformation was amazing.

The assumption that event structure in AS-nominals is associated with the verbal or the adjectival stem in turn has other consequences. As verbs and adjectives, themselves ELs, cannot have arguments as such, it follows that we must assume, within AS-nominals, a fully projected event complex, complete with whatever functional structure is responsible for the projection of argument structure. At the minimum, then, breaking or destruction when occurring as an AS-nominal, must embed a structure that includes not only break or destroy, but also a full VP and a full functional structure associated with whatever arguments break or destroy would otherwise be associated with. If we assume that e.g., (38) is the structure associated with break (transitive) or destroy, then we must assume that the structure in (39) is associated with the AS-nominals breaking or destruction:

(38) a. Kim broke/destroyed the vase
    b. [IP Kim [TP [VQ the vase [L-D break/destroy]]]] (L-D \rightarrow VP)

(39) a. Kim’s breaking/destruction of the vase
    b. [NP -tion [VQ Kim [VQ the vase [L-D break/destroy]]]]
       (L-D \rightarrow VP)

In accordance with an already established practice, L-D in (38)-(39) would become a VP, verbalized by ASP, and break or destroy, its head, will become a verb. Argument structure and event interpretation will emerge exactly as they do for active proposition with break or destroy, having an identical structure (TP aside). In turn, we may assume, for concreteness sake, that the verb, be it break or destroy merges copies through the successive functional heads in (39) to -ing or -ation, where breaking or destruction emerge, following the association of the appropriate morphological structure with the output of the head-to-head movement.

The evidence for the fact that the argument structure, for derived nominals, comes from the presence of some structure external to the nominal itself is surprisingly simple and straightforward. Consider, specifically, R-nominals, as in (40):

(40) a. the destruction was devastating
    b. the examination is over
    c. the formation is complete

R-nominals, by definition, do not have an Ev interpretation, and do not have an event argument structure. Yet, morphologically, they are clearly very
much the same creatures as AS-nominals, and must be assumed to be derived, morphologically, in an identical fashion. If we take the relevant morphological structure deriving both AS-nominals and R-nominals to be as in (8a-b), we can assume that morphological structure to be associated with the output of head-to-head movement in (39), but to be associated directly with some EI, within the conceptual array, in the case of R-nominals, as illustrated, for formalize, by (9b). Effectively, this means that a category neutral EI such as form, residing in the 1-domain of (41a) as part of the conceptual array, may be associated, in the 1-D, with an inserted nominal (and verbalizing) affix -ation, a member of the functional lexicon, to give rise to the structure in (41b). Of course, following the insertion of the relevant morphological structure formation is an N. If it is to become the head of 1-D, it will force the existence of an NP, and would only allow the projection of nominalizing functional structure, e.g., DP, NumP, etc., but not the projection of verbalizing functional structure, such as TP or ASP:

(41) a. \[ {_{1-o} \text{form}} \] 
   b. \[ {_{1-o} \quad \text{N} \quad } \]
   \[ \text{form} \quad \text{-ation} \]
   c. \[ \text{TP} \quad \text{NumP} \quad \text{NP} \quad \text{formation} \]
   d. *\[ \text{TP} \quad \text{asp} \quad \text{formation} \]

That formation, as an R-nominal, does not have any argument structure in the representation in (41) emerges directly from the derivation. There is no argument structure here, quite simply because the nominalization was, so to speak, too low, and any attempt to add argument structure to it would involve the projection of structure that is incompatible with the existence of an N-head. Nothing else needs to be said. Much, however, must be said - and has been said - by any theory which assumes that either verbs or nouns assign argument roles, be they eventive or otherwise. Such theories must assume either that nouns are special in that their argument assignment properties are optional, unlike verbs in general, or the verbs from which they are directly derived (in essence Chomsky, 1970 and much subsequent literature) or alternatively, as Grimshaw assumes, that nouns are ambiguous, and that they are not related, argument-wise, to their source verbs. None of these complications, with their empirical and conceptual inadequacies, emerge if we assume that neither the noun formation, nor the verb form embedded within it have any arguments to assign.

Supposing this to be on the right track, there is a VP (or an AP) inside all AS-Nominals, alongside full functional event structure similar to that otherwise attested in propositions. On the other hand, R-nominals are simple
nominal structures, with a nominalizing morphological structure as well as whatever compatible functional structure may co-exist with it.

That there is, indeed, a VP inside derived nominals has been, in turn, argued for extensively in a broad range of languages, including French (Valois, 1991), Hebrew (Hazout, 1990, 1995; Borer, 1993), Chinese (Fu, 1994), Russian (Schoorlemmer, 1995) among many others, as well as most recently for English (Fu, Roeper and Borer, 2001), and I will assume the fundamental correctness of these approaches. Suppose we turn, however, to another question concerning the relations between particular nominalizing affixes and the resulting properties of AS-nominals. Grimshaw (1990) claims that –ation nominals are always ambiguous between an Ev and an R reading, that –ing nominals are always Ev nominals, and that Ø-derived nominals are always R-nominals, thus crucially linking the ±Ev property with nominalizers, rather than the stems from which they are derived. As I have now argued that event structure is never associated with nominals, but specifically with the event complex which is headed by the incorporated L-stem, these generalizations, if indeed correct, must be explained.

5 Do N-Affixes Determine Event Structure?

It has been claimed by Grimshaw (ibid.) and others that different nominalizing affixes have different effect on the output derived nominals, and that specifically, the picture in (42) holds, such that Ø-nominalizers only give rise to R-nominals, -ing nominalizers only give rise to AS-nominals, and –ation is ambiguous. That Ø-nominalizers, with few exceptions, do, indeed, give rise to R-nominals is very clear from the data in (43):

(42) Grimshaw: Ø(R); -ation({R,Ev}); -ing(Ev)

(43) a. *the/John’s drive of this car
   b. *the/Mary’s walk of this dog
   c. *the/Kim’s break of the vase
   d. *the airforce’s murder of innocent civilians

13 Alas, like all generalizations concerning WF, this one, too, has counterexamples. Thus while at least some speakers reject (i)-(iii), others find them acceptable:

   i. My constant change of mentors from 1992-1997
   ii. The frequent release of the prisoners by the governor
   iii. The frequent use of sharp tools by underage children
It is less than obvious, however, that Grimshaw is correct in suggesting that 
-ing nominals are always Ev nominals, AS-nominals in our terms. Certainly, the 
-ing nominals in (44) are not result nominals, but as we have already seen, R-nominals need not be result nominals, and may be, instead, event nominals, or as the case appears to be at least for some of the nominals in (44), nominals denoting state.

(44) a. a good living, a strong craving, a strong beating, a reading, (left-
ist) leaning, (good) standing, (one) sitting, etc.
   b. Women are reared not to feel competent or gratified by the questing, the competing, the outbidding that collecting … de-
mands.
   c. (this kind of) fighting, fraternizing, parenting, writing, etc.

In turn, if, indeed, both -ing and -ation allow freely AS-nominals and R-
ominals, showing that at least for these two affixes the choice of N-affix is not the determinant of event structure, an important question concerns the absence of an AS-Nominal reading for Ø-nominalization, especially since at least prima facie, the relationship with the source verb is the most transpar-
tent, at least in (43a-c), and most so-called Ø-derived nominals do, indeed, have a salient event denotation:

(45) a. the walk lasted for five hours
    b. the jump occurred before dawn
    c. the (responsive) read took place in the law review office

I suggested that the structure for AS-nominals with either -ing or -ation is in essence as in (39b). It would appear, then, that for some reason, the structure in (46) is not available, although the structure in (47), that of R-nominal with Ø, is available:

(46) \[ \text{NP } \text{Ø NOM} \quad \text{EP} \quad \text{Kim} \quad \text{the vase} \quad \text{break}[[[\text{L-D } \rightarrow \text{VP}]]]] \]
(47) \[ \text{NP } \text{Ø } \text{break}[[[\text{Ø}]]]] \]

Viewed differently, however, the absence of AS-nominals with Ø-
morphology is fully explained, if we assume that what appears as a Ø-
morpheme is in actuality a category neutral stem, unmarked for being either a noun or a verb. In effect, we suggest, English does not have a Ø-
morpheme which mediates conversion from verbs to nouns or from nouns to verbs. Rather, English has category neutral EIs, inserted into particular structures which render them verbs or nouns, syntactically. Consider, spe-
specifically, how such an account would work for the absence of AS-nominals with neutral stems, taking break as an example. For R-nominals, the derivation is straightforward. Rather than assume a Ø-affix, as in (47), consider instead a derivation in which a category neutral EI is inserted in L-D, and L-D becomes an NP as it is embedded under nominal functional structure (e.g., DP):

(48) a. \([_{	ext{e},} \text{break}]\)  
b. \([_{	ext{e}}, \text{the }_{	ext{e},} \text{break}] \rightarrow \text{NP, } [_{	ext{e}} \text{break}] \rightarrow [_{	ext{e}}, \text{break}]\)

The derivation of a verbal break, within a propositional context, is likewise straightforward. As soon as ASP$_Q$ (or TP) project, L-D will be verbalized, and one of its constituents will be targeted as a possible head, in turn verbalized as well:

(49) a. \([_{	ext{L-D}} \text{break, Kim, vase}]\)  
b. \([_{	ext{ASP}_Q} \text{the vase }_{	ext{L-D}} \text{break, Kim, } [_{	ext{e},} \text{vase}] \rightarrow \text{ASP}_Q \rightarrow \text{VP, } [_{	ext{L-D}} \text{break}] \rightarrow [_{	ext{V}} \text{break}]\)

Consider, however, AS-nominals. We suggested that a full VP event complex is projected within AS-nominals. This means that for a nominal such as the breaking of the vase, the merger of an ASP$_Q$ with L-D is essential, to give a landing site for the vase. Likewise, a subject-of-quantity argument associated with break must project in the specifier of ASP$_Q$. Thus in attempting to derive (43d), we must start by projecting the structure in (50):

(50) \([_{\text{ASP}_Q} \text{Kim }_{\text{ASP}_Q} \text{the vase }_{\text{V}} [_{\text{e},} \text{break}] , [_{\text{e},} \text{Kim}], [_{\text{e},} \text{vase}]\)  

As in the case of (49b), ASP$_Q$ will verbalize L-D as well as its head, break. If, e.g., –ing merges above ASP$_P$ in (50), an AS-nominals does emerge. However, if indeed English does not have Ø-nominalizers, and all Ø-alternations between verbs and nouns are instances of category-neutral stems, the representation in (50) cannot become nominalized without an overt nominalizer, and an AS-nominal derivation for \([_{\text{e},} \text{break}]\) is expected to never occur. As in the case of the missing arguments for R-nominals, here as well it is hard to see how a theory which attributes role assignment to lexical entries can likewise capture these facts.

6 More on the Absence of Ø Noun-Verb Alternations
We have, now, an interesting prediction. If, indeed, English does not have \( \emptyset \)-categorizing morphology, and all stems that appear to alternate between categorial types are, in actuality, category neutral stems categorized by the syntactic structure, we predict that the great freedom attested in English which allows any noun to be inserted in a verbal frame and any verb to be inserted in a nominal frame should be only attested with respect to category neutral stems, which is to say, stems that are not associated with any category morphology.

That this is indeed the case, can be immediately illustrated by the ungrammaticality of (51b-c):

\[
(51) \begin{align*}
\text{a. } & \text{form, floor, table, chair, run, kiss, break, closet, wardrobe, telephone, brother, dog, cat, etc.} \\
\text{b. } & *\text{a formalize, *a fatten, *an enclose, *a bemoan, etc.} \\
\text{c. } & *\text{to formation, *to brotherhood, *to government}
\end{align*}
\]

The generalization here cannot be based on morphological complexity. Note that the forms in (52) are morphologically complex:

\[
(52) \text{rerun, rebound, transport, import, export, subcontract}
\]

Further, note that primary compounds do display a \( \emptyset N \leftrightarrow V \) alternation:

\[
(53) \begin{align*}
\text{a. } & \text{to grandstand, to blackboard, to chicken-wire, to wall-paper, etc.} \\
\text{b. } & \text{a white-out, a take-off, a sell-out, a buy-up, a take-over, etc.}
\end{align*}
\]

Rather, it seems that \( \emptyset N \leftrightarrow V \) alternations are possible providing the morphological head is a category neutral EI. As prefixes in English do not change category, and neither do particles, as in (53b), the head remains a category neutral stem. Likewise, in primary compounds, the head, the right member, may be category neutral (but not so in synthetic compounds, note). Some illustrations of primary compounds that cannot enter \( \emptyset N \leftrightarrow V \) alternations precisely because the right stem, the head, is not category neutral, as in (54):

\[
(54) \begin{align*}
&\text{*to company executive; *to compound director; *to school teacher; *to university professor, etc.}
\end{align*}
\]

The derivation for primary compounds as verbs such, as \textit{wallpaper} is given in (55). We may assume, specifically, that both \textit{wall} and \textit{paper} are mem-
bers of the conceptual array, being compounded by a morphological rule. In turn, the morphological rule assigns a morphological head status to the right stem, and either an N or an A category to the left stem. In turn, the entire compound, if headed by a category neutral EI, is categorized by the functional structure, as in (55b):

(55) a. [L wall…] [L paper]
   b. [L [AN wall] [L paper]] (by the compounding rule)
      i. [L [L [AN wall] [L paper]]] L → N
      ii. [LAP [L [AN wall] [L paper]]] L → V

Note that the structure in (55a-b) would be the identical one to that assigned to exocentric compounds, in essence putting forth the claim that all primary compounds in English with underived right member are syntactically exocentric.

While, of course, some counterexamples do exist, we note that of approximately 1300 denominal verbs studied by Clark and Clark (1979) and excluding instrumentals, there is a total of six counterexamples to the claim that nouns with categorial morphology do not participate in Ø-N/V alternations: to launderette, to laundress, to blockade, to allowance, to tourist, and to lover (other than blockade, all rejected by native speakers). In the instrumental class, 12 out of 117 forms listed as possible verbs are derived, including to elevator, to accelerator, to stopper, to trailer, to glider, and others, very clearly re-analyzed and re-entered as independent EI.

But see footnote 6 on the possibility that adjectives are never categorized by the structure, leaving N as the only possibility for the left member in (55).

Kiparsky (1982) argues that the Ø-affix converting verbs to nouns is unproductive and belongs to Level I morphology, while the Ø-affix converting nouns to verbs is fully productive and belongs to Level II morphology. The examples in (53b) as well as those in (54) are a straightforward counter-example to the level ordering assumed by Kiparsky, as is the ungrammaticality of to transformation and to professor. We also note that contra Kiparsky, V → N alternations are extremely common and spontaneously produced on a regular basis, including cases which one would assume should be prohibited by blocking, such as give it a think. See Borer, forthcoming, for a fuller review.

We note as an open issue here the mixed behavior of forms such as those in (i), where we have the appearance of a the nominal suffix –tion, but where there is no source morphological L-stem (or in turn, a source so drifted in meaning so as to give rise to the plausible assumption that the form has been entered separately in the encyclopedia from its erstwhile morphophonological source, as in the case of proposition). While some of these forms easily lend themselves to ‘verbalizations’, others seem more resistant, for reasons that do not seem obvious:
7 On the Growth-Potential of Theories Based on Growth

The account for the properties of R-nominals as well as for the absence of an AS-nominal reading for ‘Ø-derived’ nominals relied heavily on two assumptions. The first concerned the claim that EI, as such, do not have any formal syntactic or morphological properties. To varying degrees, this claim is the defining feature of constructionist as well as neo-constructionist approaches, including the present one. The second the assumption involved the claim that the functional structure which is associated with the assignment of all direct (event) arguments is a verbalizer (or alternatively possibly an adjectivizer), and most specifically, that it cannot be associated with an N-head. This, we note, is not a necessary assumption within a neo-constructionist approach, and in actuality, it does differentiate the account presented here from those put forth by Picallo (1991), Ouhalla (1991), and most recently Marantz (1997) and Alexiadou (1999) (and see also Harley and Noyer, 1998a,b). In all these accounts, which are neo-constructionist to varying degrees, it is assumed that in AS-nominals the L-D is headed by an N. To consider specifically Alexiadou (1999), who shares with the analysis presented here both a neo-constructionist approach to category determination, as well as the assumption that AS-nominals involve an articulated event structure separating the head from the DP, she nevertheless assumes that the relevant structure fundamentally does not have a verbalizing function, and that for e.g. destruction of the city, the structure (somewhat schematically) is as in (56a), where neither ASP (grammatical aspect) nor v, in essence an event licensing node (but not an external role assignor), are verbalizers, and hence L may be realized in situ as an N, and LP as NP, if dominated by a DP. In turn, non-event nominals involve the projection of a DP structure without the event node v (and without grammatical aspect) schematically as in (56b):

\[
\begin{align*}
\text{(56) a. } & \quad \text{L} \rightarrow \text{N} \\
\text{b. } & \quad \text{L} \rightarrow \text{N}
\end{align*}
\]

i. a. to portion, to position, to condition, to proposition, to audition, to ration, to question, to motion

b. *to nation, *to ambition, *to potion, *to notion

17 Note that Alexiadou (1999), following Marantz (1997) also continues to subscribe to the view that internal arguments (but not external ones) are assigned by the root (our EI), and not through the structure, thereby requiring a special mechanism to allow its omission in R-nominals, involving, specifically, the presence vs. absence of structural case.
Structures such as those in (56) fail, I believe, in two crucial ways. First, they entirely fail to predict the fact that only nominals that are morphologically derived from verbs (or from adjectives) may give rise to AS-nominals. There is nothing in the structure in (56a) which allows it to be sensitive to any morpho-phonological considerations. √\textit{destroy} is nominalized in the context of DP, on a par with the nominalization of \{\textit{dog}\} or \{\textit{table}\} or \{\textit{transformation}\}, or, for that matter, on a par with the nominalization of √\textit{destroy} in the R-nominal in (56b). Secondly, the representations in (56) entirely fail to predict the fact that Ø-alternations cannot occur as AS-nominals.

Ironically, (56a-b), at first sight so different from the lexicalist approach put forth by Grimshaw (1990), fail precisely where Grimshaw (1990) fails. Upon a closer look, this is not surprising, as they represent it is a syntactic execution of her very idea, endowing some nominals, but not others, with event structure. Both Grimshaw’s (1990) analysis and Alexiadou (1999)’s structures thus differ from the analysis presented here, whereby event structure is never associated with N, as such, but is always a property of an event structure embedded under a nominal head and associated with a distinct lexical head.

The analysis put forth by Alexiadou (1999) shares one more property with Grimshaw’s account, in disallowing in principle, the projection of an external argument within AS-nominals. For Alexiadou (1999), following Marantz (1997), this follows from the fact that while neither vP nor ASP P in (56a) are verbalizers, a v which assigns an external argument is a verbalizer. Thus when such a node projects, a root embedded under it would become a v, rather than an N, and a derived nominal, quite simply, would not emerge. In the analysis proposed here, and regardless of whether or not v is, indeed, the relevant functional structure for the licensing of an external argument, nominalization crucially occurs above the event complex, which is always a verbalizer, and is possible because it gives rise to a verbal event complex embedded within a nominal structure. Thus there is little reason to assume that in principle external arguments are not possible within AS-nominals, contra Marantz (1997) and Alexiadou (1999).

Empirically, much of the support for the absence of external arguments within AS-nominals comes from Chomsky’s (1970) account for the well-known ungrammaticality of (58a) with a transitive interpretation, as well as the ungrammaticality of (58b-c):

\begin{itemize}
  \item (57) a. The farmer grew the tomatoes
  \item b. The tomatoes grew
\end{itemize}
(58)  a. The growth of tomatoes (intransitive reading only)  
    b. *the farmer’s growth of tomatoes  
    c. *the growth of tomatoes by the farmer

Chomsky (1970), and following him, Marantz (1997), suggest that the ungrammaticality of (58a) with a transitive reading as well as the ungrammaticality of (58b-c) derive from the fact that transitive *grow is, in actuality, a complex form consisting of CAUSE+grow. If one assumes that CAUSE is an abstract entry which assigns an external cause role, say *v, and that *v is a verbalizer, it follows, for Marantz (1997), that *v cannot occur within AS-nominals, as its projection would lead immediately to the verbalization of the root embedded underneath it, blocking a nominal. Hence, the only possible derivation for grow would be one which does not involve *v, i.e., an intransitive derivation.

Marantz notes, nevertheless, that (59b) is grammatical, as is (59a) with a transitive derivation:

(59)  a. the destruction of the city  
    b. the enemy’s destruction of the city

To accommodate this, he assumes, along lines assumed by Grimshaw (1990) for similar structures, that the enemy’s in (59b) is a possessor, and that the possessor may have a free interpretation in cases such as (59), including an interpretation that happens to coincide with that of agent. That such an interpretation is barred for (58) follows, in turn, from the lexical semantics of the root grow which requires an external cause, not a possible interpretation for the possessor.

There are a number of problems with the analysis, however, not the least of which being the grammaticality of (60) (and see also (61) as well) already noted by Chomsky (1970) as problematic for the CAUSE analysis which he, himself, proposes:

(60)  a. Mary’s growing of the tomatoes  
    b. The growing of the tomatoes (ambiguous)

(61)  a. The navy’s sinking of the ship

---

18 We note that by appealing to the lexical semantics of grow to exclude (58) Marantz effectively resurrects a lexical semantics for roots which determines not only the internal argument of an emerging form, but also its external argument, if only by means of excluding some roots, and thus effectively some syntactic structures, in the context of some types of external arguments.
b. Bill’s melting of the wax
c. Kim’s breaking of the vase

Nor is the grammaticality of (60)-(61) an artifact of some putative difference between –ing nominals and others (see Marantz, 1999). Harely and Noyer (1998a), investigating precisely this issue, cite the following examples in which an external argument interpreted as an external causer does appear licensed within AS-nominals with –ation nominalizers, in contrast with (58):

(62) a. Kim’s accumulation of dust
    b. The accumulation of dust (ambiguous)
    c. Robin’s separation of Kim and Pat
    d. The separation of Kim and Pat (ambiguous)
    e. The government’s unification of the city
    f. The unification of the city (ambiguous)

And finally, a restriction against an external argument within AS-nominals as deriving from the impossibility of the projection of \( \nu \) has the hallmark of a linguistic universal. However in Hebrew where the forms for transitive *grow* and intransitive *grow* are morpho-phonologically related, but distinct, and each has a separate derived nominal, both are attested without any resulting ungrammaticality:

(63) a. gidul ha-‘agvaniyot (‘al yedey ha-‘ikarim)
    growth.TRANS the-tomatoes (by farmers)
    ‘The growing (trans) of tomatoes’

    b. gdilat ha-‘agvaniyot
    growth.INTRANS the-tomatoes
    ‘The growing (intrans) of tomatoes’

We therefore conclude that *growth* is rather isolated in exhibiting the behavior in (58), and that what is called for is an explanation for the exceptionality of *growth*, rather than an account which generalizes from its properties, thereby making wrong predictions for a broad range of derived nominals. What, then, could possibly be the reason for the ungrammaticality of (58)? Following the lead of Pesetsky (1995), but with a very distinct execution, we would like to propose that the ungrammaticality of (58) has a morpho-phonological, language specific source, and not a syntactic one. We note that Pesetsky’s claim, whereby *growth* is ungrammatical because it involves a Ø-affix attached to *grow*.INTRANS together with the assumption that Ø-affixation blocks all further affixation, could not possibly be adopted, or it
would rule out, incorrectly, the transitive AS-nominals associated with accumulation, separation and unification, in a parallel fashion (Pesetsky does assume that –ing is special)."

Rather, I would like to propose that grow and growth do not represent a derivational relationship, but rather, they are stem allomorphs, much like what we find in destroy/destruct(ion), progress/progrés, louse/lice, break/broke etc. We do not have here an actual derivational process, but rather, the selection of a particular allomorph from a paradigmatic set in particular morpho-phonological or morpho-syntactic environments. Thus destruct is a verb allomorph which is inserted in bound contexts, just like broke is the stem allomorph that is inserted both in past tense contexts and in bound contexts to give rise to broken. On the other hand eat is the stem allomorph that is inserted in present tense contexts and in bound contexts, to give rise to eaten. In neither case is the form eat present or broke past, or we would have to claim that –en is sometimes attached to past tense forms, and sometimes to present tense forms.

In turn, if growth is a stem allomorph inserted in nominal contexts, rather than an actually derived form, then whatever rationale applies to other category-neutral forms must apply to it – it may not be embedded within AS-nominals, quite simply because in order for an event complex, an inherent verbalizer, to become nominal, an overt nominalizer is required, but –th by definition is not such a nominalizer. Thus growth, in actuality, is an R-nominal, and the growth of the tomatoes has the same properties and the same structure as yesterday's/the return of the Jedi (*in a day) or the design of the furniture.

To support this claim, consider the distribution of nominals with -th in English which actually have a corresponding noun or adjective:

(64) a. (birth), breath, death, growth, stealth, health (appears to be an exhaustive list)

b. width, length, strength, warmth, truth, breadth, dearth (appears to be an exhaustive list)

---

The second half of Pesetsky's claim, according to which annoyance and similar nominals derived from psyche-predicates cannot be transitive, due to the presence of a Ø-causative affix which blocks -ance affixation, could not be adopted because unlike the behavior of growth, which is clearly language specific and morpho-phonologically conditioned, the behavior of annoyance is not language specific, and is not conditioned by the morpho-phonology. Thus in Hebrew, transitive nominalizations equivalent to annoyance are ungrammatical as well, although as in the case of growth, no Ø-affix could be assumed, and the transitive form and the intransitive forms are morpho-phonologically distinct.
The list here is very limited indeed, nor is –th in any sense productive in the language. Consider, more strikingly, however, the following forms (with thanks to S. Anderson, p.c.):

(65)  *lengthen, strengthen. (and note also height, heighten, R. Kayne, p.c.)

As is well known, -en attaches to adjectives to give rise to verbs:

(66)  redden, blacken, thicken, fatten, shorten, etc.

As is further well known, -en is morpho-phonologically constrained, and may not attach to adjectives which have a final sonorant, and hence (67):

(67)  a.  -en attaches to adjectives (*[+sonorant]#en)

Consider, in view of this, (65). Both long and strong could not be affixed with –en, as both end in a sonorant, and such an affixation would give rise to *longen or *strongen. Instead, we find lengthen and strengthen, and also heighten, because the adjective high is similarly constrained, and here, too, height is a stem allomorph. If, now, we assume that -th forms are stem allomorphs, inserted, in the case of lengthen and strengthen in a morpho-phonologically conditioned environment, rather than derived forms, not only do we account for (65), but we also resolve the mystery surrounding the impossibility of (58), without needing to assume that the event complex within AS-nominals is different in crucial ways from that attested in propositions.

Marantz (1997) cite one more case which appears to pattern with grow, i.e., that of rise/raise, pointing, specifically, to the ungrammaticality of cases such as those (ia), when contrasted with the grammaticality of (ibid.):

i.  a.  *Jane's raise of the crane
    b.  The rise of the sun

Note, however, that (ii) is morphologically well-formed, although it is both morphologically and semantically related to the transitive raise, and not to the intransitive rise:

ii.  I was given a raise this month
8 By Way of Summary

By way of summarizing this paper, we consider briefly a number of interesting questions which arise here, in principle, and which are clearly worth pursuing. Note, first, that categories such as V, N, as associated with terminals, may emerge from this picture as not being universal, in the sense that there may be languages which do not distinguish between nouns and verbs on the terminal level (i.e., any lexical item may be either a noun or a verb). On the other hand, the distinction between NP and VP is a universal one, and follows from the assumption that the inventory of functional structures is both limited and universal, giving rise to tense, argument structure, DP structure, etc. A stem which is neither a verb nor a noun may exist, but in the context of a VP (so verbalized by functional structure, e.g. TenseP) or in the context of an NP (so nominalized by functional structure, e.g. DetP), they will be formally equivalent to either N or V, by virtue of heading a categorically coherent constituent.

We further note that if the system outlined here concerning the licensing of the past and the future values in English is correct, and if, indeed, we are correct in assuming that functional structure is largely licensed through either the insertion of independent functional morphemes, or through head movement, then these are not inter-grammatical variations, but rather, intra-grammatical variations. This, in turn, raises the distinct possibility that there are no grammar-specific parametric settings, and instead, language variation represents a mix and match of universally available strategies, not always consistently used in any given language, but determined by the arbitrary phonological properties of the inventory of grammatical formatives.

Recalling, now our discussion of the feed/eat problem we note that the encyclopedia obviously is not a pure conceptual component but an interface level. At the very least, it has phonological representations which may tease apart some related concepts and list them separately, as arbitrarily determined by a specific language’s vocabulary. This, in turn, gives rise to typical interface questions. How does the encyclopedia relate to the conceptual system proper, and how many more language specific properties, in addition to phonological index, could it support? At least in the case of idioms, it might appear that some syntactic information might be in order, resulting precisely in the rigidity typically associated with idioms.

The problem here, then, is that the raise does not appear to have an AS-nominal derivation, rather on a par, it would appear, with ‘Ø-derived’ nominals in general, of which raise is certainly one. As such, it patterns exactly with our claim about the nature of growth, likewise, we suggested, a ‘Ø-derived’ nominal, subject to an allomorphy rule.
And finally, we note, contra many current accounts, that morphophonological representation cannot be divorced from the grammar. Any attempt to disenfranchise it, so to speak, is empirically and explanatorily costly, precisely to those very computational systems which its elimination is an attempt to simplify.
